internet

Part of the clan networking abstraction to define how to reach machines from outside the clan network over the internet, if defined has the highest priority

System

Network

❗ Experimental

This service is experimental and will change in the future.

This module is part of Clan's [networking interface](#).

Clan's networking module automatically manages connections across available network transports and falls back intelligently. When you run `clan ssh` or `clan machines update`, Clan attempts each configured network in priority order until a connection succeeds.

The example below shows how to configure a domain so server1 is reachable over the clearnet. By default, the `internet` module has the highest priority among networks.

```
1  inventory.instances = {
2      # Direct SSH with fallback support
3      internet = {
4          roles.default.machines.server1 = {
5              settings.host = "server1.example.com";
6          };
7          roles.default.machines.server2 = {
8              settings.host = "192.168.1.100";
9          };
10     };
11 };
```

Roles

The internet service has the following roles:

- default

Options for the `default` role

host

ip address or hostname (domain) of the machine

Type: `string`

Default:

`""`

Declared in: [clanServices/internet/default.nix](#)

jumphosts

optional list of jumphosts to use to connect to the machine

Type: `list of string`

Default:

`[]`

Declared in: [clanServices/internet/default.nix](#)
